Canadian Technical Report of Fisheries and Aquatic Sciences

Technical reports contain scientific and technical information that contributes to existing knowledge but which is not normally appropriate for primary literature. Technical reports are directed primarily toward a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of Fisheries and Oceans Canada, namely, fisheries and aquatic sciences.

Technical reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in the data base *Aquatic Sciences and Fisheries Abstracts*.

Technical reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page.

Numbers 1-456 in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925.

Rapport technique canadien des sciences halieutiques et aquatiques

Les rapports techniques contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui ne sont pas normalement appropriés pour la publication dans un journal scientifique. Les rapports techniques sont destinés essentiellement à un public international et ils sont distribués à cet échelon. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques de Pêches et Océans Canada, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports techniques peuvent être cités comme des publications à part entière. Le titre exact figure au-dessus du résumé de chaque rapport. Les rapports techniques sont résumés dans la base de données *Résumés des sciences aquatiques et halieutiques*.

Les rapports techniques sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre.

Les numéros 1 à 456 de cette série ont été publiés à titre de Rapports techniques de l'Office des recherches sur les pêcheries du Canada. Les numéros 457 à 714 sont parus à titre de Rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715 à 924 ont été publiés à titre de Rapports techniques du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 925.

165	INDEX	186

ABSTRACT

167 Ricard, D., Gomez, C., Emberley, J. and Regnier-McKellar, C. 2021. Marine Fish and Invertebrate
168 Atlas: Summarizing Geographic Distribution, Population Indices and Environmental
169 Preferences in the Scotian Shelf and Bay of Fundy (1970-2020). Can. Tech. Rep. Fish. Aquat.
170 Sci. nnn: viii + 191 p.

171 The summer groundfish research vessel survey on the Scotian Shelf and in the Bay of
172 Fundy started in 1970 and was designed to measure the distribution and abundance of
173 major commercial fish species. Over time, additional information on non-commercial species
174 was collected, and allowed considerable insight into ecosystem function and structure, as
175 documented in many primary publications whose analyses used the survey data. The same
176 groundfish survey database has also been used to produce species status reports, atlases of
177 species distribution and remains an essential source of information for stock assessments in the
178 Maritimes Region of Fisheries and Oceans Canada. This report builds on previous work and
179 former atlases by updating a comprehensive suite of indices to assess population status and
180 environmental preferences of 104 species. For each species, trends in geographic distribution
181 and biomass or abundance were plotted. The spatial extent of distribution was plotted over
182 time to gauge how the area occupied has changed. The relationship between abundance or
183 biomass and spatial extent reflected whether the species distribution expands when abundance
184 or biomass increases. Length frequencies over time depicted any changes in mean size. The
185 plots of condition over time revealed whether individual fish are fatter or thinner than their long
186 term mean. Depth, temperature and salinity preferences were estimated to gauge the range
187 of suitable environmental parameters for each species. Finally, for each stratum, the slope
188 describing how local density varies with regional abundance was estimated. The reproducible
189 set of tools provided in this report constitutes a stepping stone to conduct other ecological
190 analyses using the summer groundfish research vessel survey data by fostering reproducibility
191 and transparency of ecological information collected and reported annually. Recognizing the
192 diversity of approaches for visualizing and mapping fish and invertebrates in the Scotian Shelf
193 bioregion, we recommend the development of a regional community of practice to compare and
194 evaluate approaches for mapping, interpolating and/or modelling fish and invertebrates so future
195 publications and advice can lead to more comparable work and consistent science advice to
196 support processes such as marine spatial planning.

RÉSUMÉ

198 Ricard, D., Gomez, C., Emberley, J. and Regnier-McKellar, C. 2021. Marine Fish and Invertebrate
199 Atlas: Summarizing Geographic Distribution, Population Indices and Environmental
200 Preferences in the Scotian Shelf and Bay of Fundy (1970-2020). Can. Tech. Rep. Fish. Aquat.
201 Sci. nnn: viii + 191 p.

202 Le relevé estival par navires de recherche sur le poisson de fond sur le plateau néo-écossais
203 et dans la baie de Fundy a débuté en 1970 et visait à mesurer la répartition et l'abondance
204 des principales espèces de poissons commerciales. Au fil du temps, des informations
205 supplémentaires sur les espèces non commerciales ont été recueillies et ont permis de mieux
206 comprendre la fonction et la structure de l'écosystème, comme le montrent de nombreuses
207 publications primaires dont les analyses ont utilisé les données d'enquête. La même base
208 de données sur les relevés du poisson de fond a également été utilisée pour produire des
209 rapports sur la situation des espèces, des atlas de la répartition des espèces et demeure une
210 source essentielle d'information pour les évaluations des stocks dans la région des Maritimes
211 de Pêches et Océans Canada. Ce rapport s'appuie sur des travaux antérieurs et d'anciens
212 atlas en mettant à jour une série complète d'indices pour évaluer l'état de la population et les
213 préférences environnementales de 104 espèces. Pour chaque espèce, les tendances de la
214 répartition géographique et de la biomasse ou de l'abondance ont été tracées. L'étendue spatiale
215 de la distribution a été tracée au fil du temps pour évaluer comment la zone occupée a changé.
216 La relation entre l'abondance ou la biomasse et l'étendue spatiale indique si la répartition
217 des espèces augmente lorsque l'abondance ou la biomasse augmente. Les fréquences de
218 longueur au fil du temps représentaient tout changement dans la taille moyenne. Les graphiques
219 de l'état au fil du temps ont révélé si les poissons individuels sont plus gros ou plus minces
220 que leur moyenne à long terme. Les préférences en matière de profondeur, de température
221 et de salinité ont été estimées pour évaluer la gamme de paramètres environnementaux
222 appropriés pour chaque espèce. Enfin, pour chaque strate, la pente décrivant comment la
223 densité locale varie avec l'abondance régionale a été estimée. L'ensemble d'outils reproductibles
224 fournis dans ce rapport constitue un tremplin pour effectuer d'autres analyses écologiques
225 à l'aide des données du relevé estival des navires de recherche sur les poissons de fond
226 en favorisant la reproductibilité et la transparence de l'information écologique recueillie et
227 rapportée annuellement. Reconnaissant la diversité des approches de visualisation et de
228 cartographie des poissons et des invertébrés dans la biorégion du plateau néo-écossais, nous
229 recommandons le développement d'une communauté de pratique régionale pour comparer et
230 évaluer les approches de cartographie, d'interpolation et / ou de modélisation des poissons
231 et des invertébrés afin conduire à des travaux plus comparables et à des avis scientifiques
232 cohérents pour soutenir des processus tels que la planification de l'espace marin.

233

1 Introduction

234 The summer (July-August) groundfish research vessel survey on the Scotian Shelf and in the
235 Bay of Fundy was started in 1970 by Fisheries and Oceans Canada Maritimes Region. The
236 survey was originally designed to measure the distribution and abundance of major commercial
237 fish species. Over time, information on non-commercial species was also collected. The
238 groundfish survey database storing the information collected during the annual survey provides
239 the main source of fisheries-independent information for marine species in the region. This
240 information is routinely used to support stock assessments, to produce species status reports
241 and has been previously used to publish atlases of species distribution.

242 The current document is an update of an earlier report (Ricard and Shackell 2013) that built
243 on former atlases by updating a comprehensive suite of derived indices for 104 species to
244 assess population status and, when feasible, environmental preferences. The information
245 collected during the survey is stored in a relational database management system archived
246 at Fisheries and Oceans Canada Maritimes Region which contains detailed information about
247 the sampling locations and the associated catch. Tow-level survey data is also publicly available
248 from the Ocean Biogeographic Information System (DFO 2016) and from the Open data portal
249 supported by the federal government (DFO 2021). The present atlas builds upon the work done
250 by Fisheries and Oceans colleagues from the northern Gulf of St. Lawrence (Bourdages and
251 Ouellet 2012), southern Gulf of St. Lawrence (Benoît et al. 2003) and on earlier work in the
252 Scotian Shelf (Simon and Comeau 1994; Horsman and Shackell 2009).

253 To facilitate updates and foster collaboration on the analyses of the survey data, the computer
254 code necessary to extract the data, to perform the analyses presented herein, and to reproduce
255 and update the current document is made available in a git repository (Ricard and Gomez 2021).

256 The survey area covers three major Northwest Atlantic Fisheries Organization (NAFO) zones
257 that divide the Scotian Shelf into the colder east 4V and 4W (strata 440-466) and warmer
258 west 4X (strata 470-495). For each species, temporal trends in geographic distribution and,
259 when possible, biomass are plotted. Some caution is required in interpreting the results
260 obtained for several taxa due to low sample size as explained later in the text. A full ecological
261 interpretation of trends is beyond the scope of this report. Other documents stemming from peer-
262 reviewed scientific processes under the auspices of the [Canadian Science Advisory Secretariat](#)
263 (CSAS) provide further descriptions of spatio-temporal trends in different indicators and put the
264 information collected during the summer groundfish research vessel survey in a more focused
265 context (see for example Clark and Emberley (2011)).

266

2 Methods

267 2.1 Survey Description

268 The survey is conducted annually in July-August and covers the Scotian Shelf and the Bay of
269 Fundy (Figure 2). It normally involves two separate two-week trips on board an offshore fisheries
270 vessel from the Canadian Coast Guard.

271 A number of changes in fishing gear type and vessels used occurred since the onset of sampling
272 activities (Clark and Emberley 2011). Comparative fishing experiments were conducted when
273 those changes in survey platforms took place. A timeline of the survey platforms can be found in
274 Figure 1.

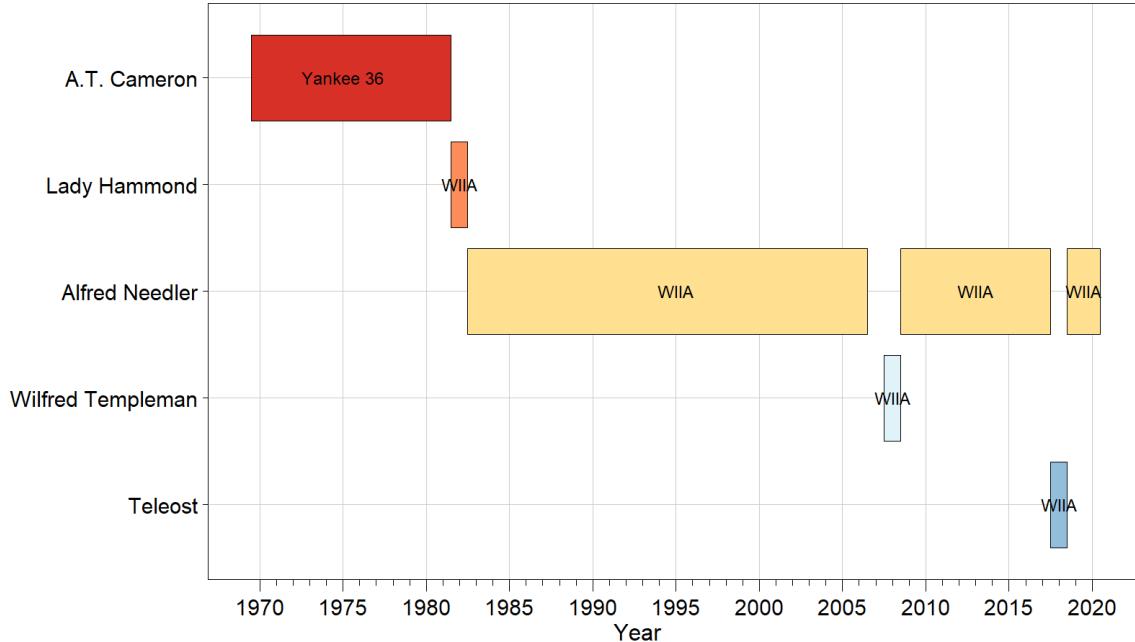

Figure 1. Timeline of vessels and gears used in the Maritimes Region summer survey.
Comparative fishing experiments are indicated by gray bars linking two fishing platforms.

275 2.2 Sampling Design

276 The summer survey covers divisions 4V, 4W and 4X of the Northwest Atlantic Fisheries
277 Organization (NAFO) which includes the Scotian Shelf and the Bay of Fundy. The eastern limit of
278 the survey is the Laurentian Channel and the western limit is the Fundian Channel (Figure 2).

279 The survey follows a stratified random design (Doubleday and Rivard 1981; Lohr 1999)
280 (Figure 3). The number of tows conducted in each stratum is approximately proportional to the
281 surface area of the stratum. The targeted area covered by the survey has remained constant
282 since its inception, with the exception of additional deeper strata that were only sampled a few
283 times since 2000. Because the sampling of the deeper strata is opportunistic and irregular, the
284 analyses presented herein only include strata 440 to 495 which cover NAFO Divisions 4V, 4W
285 and 4X (Figure 3 and Table 1).

286 The basic sampling unit of the survey is a 30-minute fishing tow conducted at a speed of 3.5
287 knots. This yields a distance towed of 1.75 nautical miles.

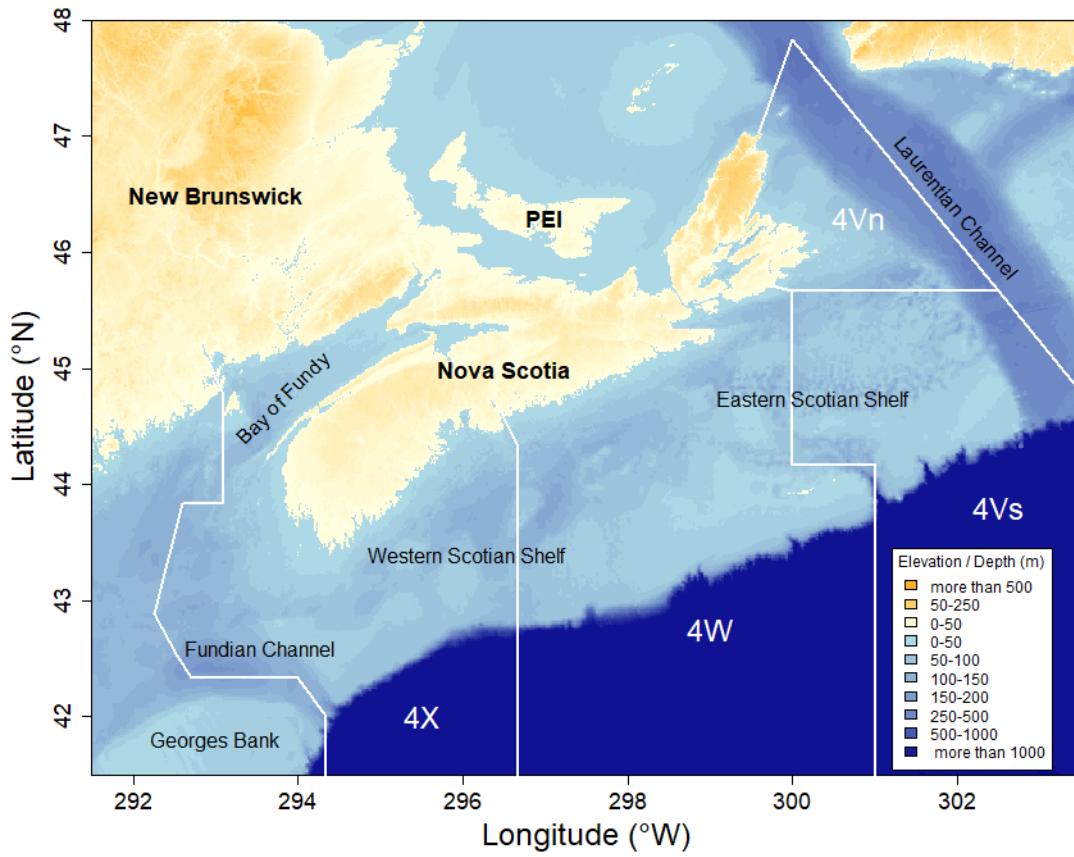

Figure 2. Map of the Scotian Shelf and Bay of Fundy where the DFO Maritimes summer survey takes place. The bathymetry presented here is the 15 arc-second gridded data set from the General Bathymetric Chart of the Oceans ([GEBCO](#)). Geographical locations of interest and the boundaries of relevant NAFO Divisions are also shown on the map.

Table 1. Summer survey strata details. The strata used in the analyses are presented separately for NAFO Divisions 4Vn, 4VsW and 4X. For each stratum, the depth range in fathoms and the surface area in square kilometers are reported.

NAFO Div.	Stratum	Depth range (fathom)	Area (km ²)
4Vn	440	101-200	924
	441	51-100	1000
	442	11-49	1437

NAFO Div.	Stratum	Depth range (fathom)	Area (km²)
4VsW	443	11-49	1318
	444	51-100	3925
	445	101-200	1023
	446	101-200	491
	447	11-49	1616
	448	11-49	1449
	449	51-100	144
	450	51-100	383
	451	101-200	147
	452	101-200	345
	453	101-200	259
	454	51-100	499
	455	11-49	2122
	456	11-49	955
	457	51-100	811
	458	11-49	658
	459	11-200	3148
	460	51-100	1344
	461	101-200	1154
	462	51-100	2116
	463	11-49	302
	464	11-50	1297
	465	51-100	2383
	466	101-200	226

NAFO Div.	Stratum	Depth range (fathom)	Area (km ²)
4X	470	51-100	920
	471	101-200	1004
	472	51-100	1249
	473	11-49	265
	474	11-49	161

	485	51-100	1582
	490	11-49	601
	491	51-100	687
	492	51-100	1086
	493	11-49	533
	494	11-49	417
	495	11-49	584

288 After each tow the catch is sorted by species and weighed. Each fish caught is then measured,
 289 and further sampling of individual fish weight, maturity status and age are performed for different
 290 length classes. When catches exceed 300 individuals, a random sub-sample is used to obtain
 291 the length and weight measurements.

292 2.3 Taxonomic Levels

293 Fish species caught during the surveys are identified by trained scientific personnel and their
 294 scientific name is determined. An internal species code used in the relational database is
 295 reported for each species (Losier and Waite 1989).

296 By its nature as a bottom trawl, the fishing gear used in the survey catches certain species
 297 better than others. To ensure that meaningful ecological information can be extracted from
 298 catch samples, we report the catch records for the subset of species that are caught reliably
 299 by the gear. To appear in this atlas, a species must have had a minimum of 10 observations over
 300 the duration of the survey activities. While both catch abundance and weight are recorded, the
 301 weight of species that appear at low abundances is often recorded as zero in the earlier parts of
 302 the survey when scales of appropriate precision were not available.

303 We divided the species caught into five categories based on 1) their taxonomic classification,

Figure 3. Map of the summer survey strata 440 to 495.

304 2) the number of recorded observations, and 3) their period of valid identification (Table 2).
 305 Category "LF", for "long frequent", was assigned to species that have more than 1000 records
 306 since 1970 and have been consistently identified since the onset of the survey. Category
 307 "LI", for "long intermediate", was assigned to species that had between 1000 and 200 catch
 308 records. Rare and elusive species (those with less than 200 catch records over the duration
 309 of the survey) are also reported but to a lower level of analytical details (Category "LR", for
 310 "long rare"). Category "SF", for "short frequent", was assigned to invertebrate species that were
 311 consistently sampled only since 1999 (Tremblay M. J. 2007). And category "SR", for "short rare"
 312 for invertebrate species consistently sampled only since 1999 and with less than 200 catch
 313 records. To ensure concordance with authoritative taxonomic information, the AphiaID from the

Table 2. Taxonomic levels used to determine the analytical treatment for each species.

Category	Name	Description
L	long - consistently identified since the onset of the survey in 1970	
LF	long frequent	species that have more than 1000 catch records
LI	long intermediate	species that had between 1000 and 200 catch records
LR	long rare	species with less than 200 catch records
S	short - invertebrate species that were consistently sampled only since 1999	
SF	short frequent	species with more than 200 catch records
SR	short rare	species with less than 200 catch records

³¹⁴ World Register of Marine Species (Appeltans et al. 2012) is included for the different species
³¹⁵ presented in this document (Table 3) .

Table 3. List of species included in the Atlas. For each taxonomic order and class, each species is listed in the table, its taxonomic family and scientific name is provided, along with its French and English common names, the species code used in the survey database, its AphiaID with a link to the World Registry of Marine Species, its number of catch records in the survey database and its classification category as defined in section 2.3.

316 **2.4 Analyses**

317 The Oracle relational database where all survey data are stored and archived is accessible from
318 the Bedford Institute of Oceanography in Dartmouth, Nova Scotia. Queries written in Structured
319 Query Language (SQL) are used to extract the data from the production server and to create the
320 data products used in all subsequent analyses. Catch records classified as "valid" (i.e. coming
321 from a representative tow without damage to the net) are used in the current analyses. To make
322 the available samples comparable, catch number and weight for each species was standardized
323 for the distance towed.

324 All data processing and analyses were conducted using the R software (R Core Team 2020)
325 using packages gstat (Pebesma 2004), PBSmapping (Schnute et al. 2019), RODBC (Ripley
326 and Lapsley 2019), spatstat (Baddeley 2015), maptools (Bivand and Lewin-Koh 2020), rgeos
327 (Bivand and Rundel 2020), classInt(Bivand 2020), RColorBrewer(Neuwirth 2014), MASS (Ripley
328 et al. 2020), worms (Holstein 2018), and tidyverse (Wickham 2019). The present document is
329 rendered as a Technical Report using the csasdown R package developed and maintained by
330 Fisheries and Oceans Canada scientists (Anderson et al. In press).

331 **2.4.1 Geographic distribution of catches**

332 Spatial interpolation of catch biomass (kg/tow) was done using a weighting inversely proportional
333 to the distance (inverse-distance weighted, IDW), using function "idw" of the spatstat R package
334 (Baddeley 2015). The IDW method was used with a power parameter value of 10.

335 **2.4.2 Biomass indices**

336 For each species, stratified random estimates of catch biomass (Smith 1996) were computed for
337 each year. Yearly estimates of the standard error were also computed.

338 **2.4.3 Distribution indices**

339 For each Category L, I and S fish species, the minimum area required to account for 75% and
340 95% of the total biomass were computed (D75% and D95%). These measures of distributions
341 were computed for each year by using the Lorenz curve of mean stratum-level catch estimates
342 and the area of occupied strata (Swain and Sinclair 1994; Swain and Morin 1996).

343 **2.4.4 Length frequencies**

344 The length frequency distribution of catch (the stratified numbers-at-length) is tabulated for each
345 seven-year period (1970-2009), and last ten-year period (2010-2020).

346 **2.4.5 Length-weight relationship and condition factor**

347 The relationship between the weight and the length of fish was estimated using the following
348 non-linear isometric relationship:

$$W = \alpha L^\beta$$

349 where W is the total weight (g), L is the length (cm), and, α and β are the parameters to be
350 estimated.

351 Average fish condition (C) was computed as:

$$C = \frac{W}{\alpha L^\beta}$$

352

353 **2.4.6 Depth, temperature and salinity distribution of catches**

354 For each category L species, We followed the methods developed by (Perry and Smith 1994)
355 and generated cumulative frequency distributions of depth, temperature and salinity of survey
356 catches.

357 **2.4.7 Density-dependent habitat selection**

358 We followed the methods of (Myers and Stokes 1989) to evaluate how fish abundance in each
359 stratum varied with overall temporal fluctuations of population abundance.

360 For each category L species, we fitted a model of the relationship between stratum-level density
361 and overall abundance (the yearly stratified random estimate of abundance, defined above).
362 To properly use the observations of zero catch while accounting for the logarithmic distribution
363 of catch abundance, we implemented the model as a generalised linear using a log link and a
364 Poisson error distribution:

$$Y_{h,i} = \alpha_{h,i} Y_i^{\beta_{h,i}}$$

365 where, $y_{h,i}$ is the average abundance of stratum h in year i , and $\alpha_{h,i}$ and $\beta_{h,i}$ are the fitted
366 parameters. The estimated parameter $\beta_{h,i}$ is referred to as the “slope parameter” and indicates
367 whether stratum-level density is positively ($\beta_{h,i} <= 0$), negatively ($\beta_{h,i} >= 0$) or negligibly
368 ($\beta_{h,i} \approx 0$) related to population abundance.

369 To estimate the suitability of each stratum, the median abundance observed during the years
370 that are in the top 25% of yearly estimates is used. We combine the slope parameter estimates
371 from the above model with the median abundance to identify strata that have consistently high
372 abundance and whose local density is weakly related to fluctuation in population abundance
373 ($\beta_{h,i} \approx 0$). Preferred strata are identified for each category L species.

374 **2.5 Description of Figures**

375 **2.5.1 Type A**

376 For Category L and S species:

377 Spatial distribution of catch-per unit of effort, (CPUE, kilograms per tow) in July-August for the
378 Bay of Fundy and Scotian Shelf in five-year periods. Spatial interpolation between tows was
379 done using Inverse Distance Weight (IDW). The probability of occurrence (proportion of tows with
380 catch records for a given species) was also reported for each five-year period.

381 For Category LR and SR:

382 Location of tows with catch over the period 1970-2020 (Type LR) or the period 1999-2020 (Type
383 SR). Location of tows with catch over the period 1970-2020 (Type LR) or the period 1999-2020
384 (Type SR).

385 **2.5.2 Type B**

386 For Category L, S and I species:

387 Stratified random estimate of CPUE (left panel), distribution indices (D75% and D95%, the
388 minimum area containing 75% and 95% of biomass, middle panel), and distribution vs. weight
389 per tow (right panel). The stratified random mean is plotted as a solid line with the 95%
390 confidence region indicated by the solid grey line. The overall mean is plotted as a grey
391 horizontal line and the overall mean plus or minus 50% of the standard deviation appear as
392 horizontal dashed lines. In all three panels, the early years appear in blue and the last years
393 appear in red. The predictions from a loess estimator are overlaid on the distribution indices
394 (middle panel). The Pearson correlation coefficient between D75% and biomass, and its
395 statistical significance, are also reported in the right panel.

396 **2.5.3 Type C.**

397 Length frequency distribution for NAFO divisions 4X and 4VW. A smoothed length frequency
398 distribution is shown for each 7-year periods covered by the surveys.

399 **2.5.4 Type D.**

400 Average fish condition for all fish lengths (black dots and black line), large fish (thick gray line),
401 and small fish (thin gray line). Fish condition is presented for NAFO divisions 4VW (right panel)
402 and 4X (left panel).

403 **2.5.5 Type E.**

404 Cumulative frequency distributions of depth, temperature and salinity at all sampled locations
405 (thick solid line) and at fishing locations with catch records (thin dashed line). The depth,
406 temperature and salinity associated with 5%, 25%, 50%, 75% and 95% of the cumulative catch is
407 shown in tabular fashion on the bottom right panel.

408 **2.5.6 Type F.**

409 Slopes estimates from the density-dependent habitat selection model (y axis) plotted versus
410 the median abundance during the top 25% of years. The red box indicates strata of particular
411 importance for a species by identifying slopes that are within a standard error from zero and that
412 are within the top 25% of median abundance. Each stratum is identified on the plot by the last
413 two digits of its number.

414 **3 Results**

415 The plots generated for each species are presented in the Appendix.

416 **3.1 Summary of successful tows by year and stratum**

417 A total of 9080 representative tows were conducted for the period spanning from 1970 to 2020
418 (Figure 4).

419 Tables 4, 5 and 6 present the number of tows conducted in each stratum and year.

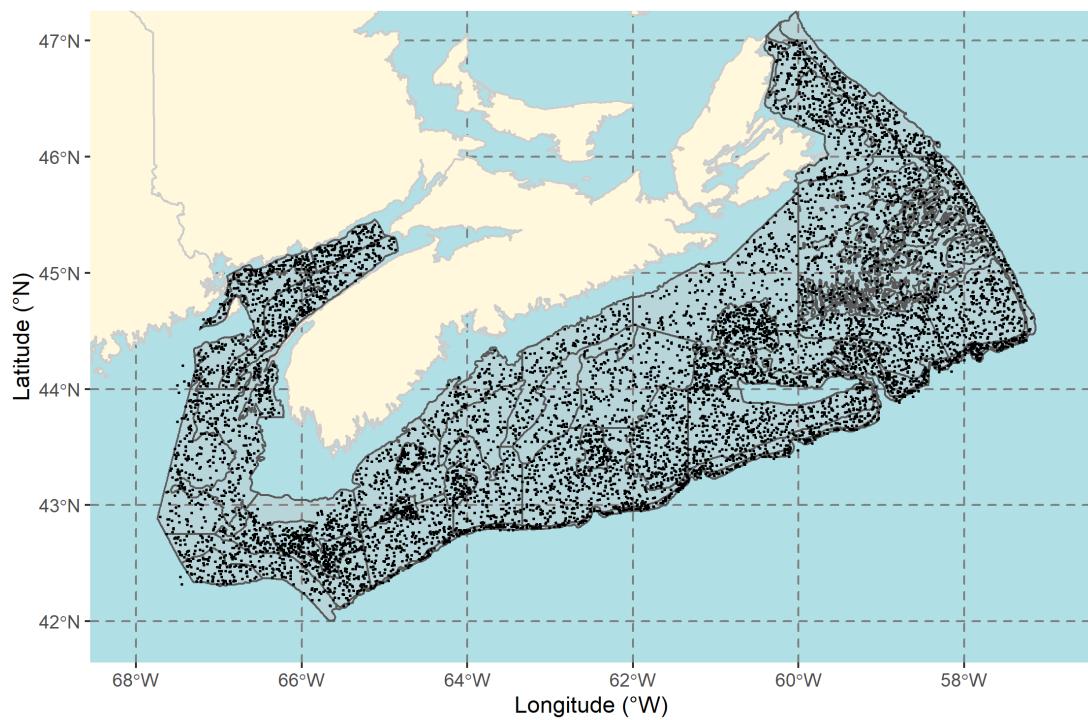

Figure 4. Map of the 9080 representative tows in the Summer survey from 1970 to 2020.

Table 4. Number of representative tows conducted in each stratum during the period 1970 to 1989.

420 **3.2 Distribution of depth, bottom temperature and bottom salinity from survey tows**

421 The depth, bottom temperature and bottom salinity cumulative frequency distribution for the
422 survey are presented in Figure 5.

Figure 5. Cumulative frequency distribution of depth, bottom temperature and bottom salinity of representative sets from the summer survey.

423

4 Discussion

424 This report builds on previous work and former atlases by updating a comprehensive suite of
425 indices to give a snapshot of population status and environmental preferences of 104 fish and
426 invertebrate species. The current document is not meant to replace stock assessments, species-
427 specific analyses of abundance, biomass and distribution, or any targeted attempts to integrate
428 information about species or group of species from the wide and disparate sources of data about
429 marine organisms in the area covered by the DFO Maritimes summer trawl survey. It is rather
430 meant to provide a reproducible set of tools to extract and visualize the information collected
431 in the summer groundfish research vessel survey. It is hoped that this document can provide a
432 stepping stone to conduct other ecological analyses using the trawl survey data and increase
433 reproducibility and transparency of ecological information collected annually.

434 **4.1 Diversity of approaches used for mapping fish and invertebrates in the Scotian Shelf
435 bioregion**

436 Different methods have been applied in the Northwest Atlantic, and specifically on the Scotian
437 Shelf bioregion, to map fish and invertebrate species distribution. The present report, for
438 example, builds upon the atlas of important habitat developed to map the persistence of relatively

439 high biomass for key fish species using the summer groundfish research vessel survey (Horsman
440 and Shackell 2009). Important habitat was obtained by interpolating observed weight per each
441 species using an inverse-distance weighted (IDW) methodology, and calculating areas with
442 relatively persistent high biomass for periods representing different fishery management eras.
443 To compliment information from this atlas, including additional representations of biomass and
444 diversity, a similar IDW interpolation mapping procedure was followed by Smith et al. (2015),
445 Ward-Paige and Bundy (2015), and Bundy et al. (2017). The summer groundfish research vessel
446 survey is typically conducted during the month of July. However, from the fall of 1978 through to
447 the spring of 1985, DFO also conducted spring and fall surveys using the same sampling design.
448 This unique seasonal data was used to map the seasonal spatial distribution of key demersal
449 and other fish species using IDW interpolation on the Scotian Shelf from the spring, summer
450 and fall between 1978 and 1985 (Smith et al. 2015). Following recommendations provided by
451 Kenchington and Kenchington (2017), the spatial distribution of three indicators of biodiversity
452 for fish and invertebrates were mapped using IDW interpolation to identify areas with persistently
453 high values across fishery management eras, and compared with areas of persistently high
454 abundance for selected species (Ward-Paige and Bundy 2015). This analysis revealed a lack of
455 consistent relationships between areas of persistent high diversity and persistent high biomass,
456 suggesting that both can be used as independent and important spatial indicators of the system
457 (Ward-Paige and Bundy 2015). Groupings of fishes and invertebrates based on size, habitat
458 and feeding guild, were also mapped using IDW interpolations to identify hotspots of functional
459 group diversity (Bundy et al. 2017). This analysis revealed a spatially and temporally variable
460 distribution of functional diversity across the Scotian Shelf with notable areas of high and low
461 diversity (Bundy et al. 2017). Top quintiles of each functional group using the IDW approach
462 were used as representative layers for fish and invertebrates in the MPA Network design in the
463 Scotian Shelf Bioregion (Serdynska et al. In press). IDW interpolation methods have also been
464 used to map the distribution of individual species such as sea cucumbers (*Cucumaria frondosa*)
465 in the Scotian Shelf bioregion (Shackell et al. 2013), and sea scallop (*Placopecten magellanicus*)
466 in Georges and Browns Bank (Hubley et al. 2014).

467 Species Distribution Modelling (SDM), instead of IDW, can also be used to evaluate spatio-
468 temporal dynamics by predicting and understanding past, present and future distribution
469 of species using environmental predictors (Robinson et al. 2017). A variety of modelling
470 approaches are being implemented in Maritimes Region to map and predict fish and invertebrate
471 species distribution by incorporating environmental predictors to account for seasonal and
472 temporal variability. For example, a stock assessment of snow crab (*Chionoecetes opilio*) on
473 the Scotian Shelf used data from the snow crab survey from 2005 to 2018 to map spatial data
474 products for this stock, including annual predicted interpolations of potential habitat using
475 Generalized Additive Models (GAM) and several environmental covariates including depth,
476 curvature, slope, species composition, and annual temperature (Zisserson et al. 2019). Sea
477 scallop predicted habitat using Maximum Entropy (MaxEnt) models were computed for German
478 Bank using data compiled via benthic habitat mapping and seafloor geotechnical surveys in
479 2006, 2009, and 2010 (Brown et al. 2012). Predictions in the Scotian Shelf bioregion and the
480 Northeast United States using datasets from DFO and the National Oceanic and Atmospheric
481 Administration from 1993 to 2012 also predicted sea scallop habitat at a wider scale based
482 on three scenarios of seasonal temperature and salinity climatologies (NOAA) (Lowen et
483 al. 2019). Offshore American lobster stock assessments (*Homarus americanus*) used data
484 from the RV, DFO Georges Bank, and National Marine Fisheries Service (NMFS) Northeast
485 Fisheries Science Center (NEFSC) bottom trawl surveys (1970 to 2015) to predict species

486 distribution using boosted regression trees and several environmental predictors (bathymetry,
487 slope, curvature, and annual temperature interpolations) (Cook et al. 2017). Information on
488 the potential for recovery of cusk (*Brosme brosme*) used data from the bottom longline Halibut
489 industry survey and Cusk absences in the Summer groundfish research vessel survey from
490 1998–2013 to predict suitable habitat using GAM, MaxEnt, and random forest models and
491 several physical environmental variables (e.g. complexity, benthic current stress and complexity,
492 temperature, salinity, primary production, chlorophyll, suspended matter) (Harris et al. 2018).
493 Atlantic halibut (*Hippoglossus hippoglossus*) assessments using Summer groundfish research
494 vessel survey and NOAA survey data from 2001 to 2013 predicted juvenile habitat using MaxEnt
495 model and environmental predictors (bathymetry, slope, bottom temperature) (French et al.
496 2018). Persistent areas of high Atlantic halibut juvenile abundance were predicted using data
497 from 27 bottom trawl surveys combined (NMFS and DFO) from 1978 to 2013 and applying
498 Bayesian hierarchical spatiotemporal models with two environmental predictors (depth and
499 temperature) (Boudreau et al. 2017).

500 These examples of mapping efforts in Maritimes Region showcase the diversity of approaches
501 relevant to a variety of important research questions and management applications. Approaches,
502 methods, datasets, and environmental predictors are selected based on individual project
503 research questions, and considerations for each species, communities or stock. This allows
504 research groups to maintain innovation and keep up with emerging methods and technologies to
505 improve assessments, predictions, and ultimately, science advice. The diversity of approaches
506 also leads to complexity when looking across studies as each data compilation and predictive
507 method carries its own independent assumptions and can lead to different spatial outputs.

508 **4.2 Interpreting spatial results for marine spatial planning purposes**

509 Fisheries and Oceans Canada is leading a marine spatial planning process that brings together
510 relevant authorities and stakeholders to better coordinate how we use and manage marine
511 spaces to achieve ecological, economic and social objectives. Operationalizing marine spatial
512 planning includes a series of steps, including the process of analyzing existing conditions
513 by collecting and mapping information about ecological, environmental and oceanographic
514 conditions (Ehler and Douvere 2009; Agardy et al. 2011). Mapping the distribution of species
515 is critical for the implementation of spatial management and as a first step in marine spatial
516 planning processes. Species distribution have supported the identification of important sites for
517 a given species or areas of high richness and diversity, which in turn can be used to inform siting
518 decisions of new activities such as Marine Protected Areas (MPA), aquaculture sites or wind
519 turbines. In the Scotian Shelf bioregion, mapping species distributions has been used to highlight
520 areas of high biological diversity to support the identification of Ecologically or Biologically
521 Significant Areas (Ricard and Shackell 2013; Ward-Paige and Bundy 2015), to distinguish
522 important and persistent habitat of significant species and functional groups to support MPA and
523 conservation planning (Horsman and Shackell 2009; Smith et al. 2015; Ward-Paige and Bundy
524 2015; Bundy et al. 2017), to identify important habitat for Species at Risk (Harris et al. 2018) and
525 to highlight reserves for data-poor invertebrate fisheries (Shackell et al. 2013). Mapping species
526 distribution has also been used to illustrate multi-decadal scale projections of changes in species
527 distribution in the context of climate change and adaption (Stanley et al. 2018; Greenan et al.
528 2019).

529 In support of the marine spatial planning process, a public web-based atlas with relevant
530 geospatial information is being developed to support decision-making. This Atlantic Canada-
531 wide compilation of data and information will be a web-based, public platform with interactive
532 maps of ocean ecosystems, human uses and management areas. This atlas cannot host the
533 vast diversity of products and mapping approaches available in Maritimes Region. Consequently,
534 we recommend that data products presented in this report should not be used for the atlas until
535 an evaluation of the spatial information available and used in the past, is conducted.

536 This diverse portfolio of approaches and applications is not unique to the Maritimes Region. A
537 recent review of global distribution modelling efforts recommended the adoption of a consistent
538 framework that integrates multi-model approaches and a clear expression of errors and
539 uncertainties (Robinson et al. 2017). In this context, Pacific Region has developed two initiatives
540 to enable consistency and frequent publication, reproducibility, and transparency. One initiative
541 developed a reproducible report to give a synthesis of data availability, population trends, fishing
542 trends, growth and maturity patterns for 113 groundfish species in British Columbia to support
543 stock assessment (Anderson et al. 2019). The second initiative developed a SDM framework
544 that was applied to twelve species on Canada's Pacific coast as part of the Regional Response
545 Plan (Nephin et al. 2019). The Maritimes and Gulf region, through this and past reports, are also
546 using similar reproducible approaches to facilitate annual updates and transparency (Ricard and
547 Shackell 2013; Ricard et al. 2021).

548 Recognizing the diversity of approaches for mapping fish and invertebrates in the Scotian Shelf
549 bioregion, we recommend the development of a regional community of practice to compare
550 and evaluate approaches for mapping, interpolating and/or modelling fish and invertebrates
551 so future publications and advice related to spatial outputs can lead to more comparable work
552 and consistent science advice to support processes such as marine spatial planning. At the
553 international level, guidelines and standards related to appropriate variables and methods
554 for mapping and modeling species and communities of deep-sea habitats were proposed to
555 encourage the production of publications that will lead to more comparable work (Kenchington
556 et al. 2019). Similar general guidance for how groups approach mapping activities would be a
557 worthwhile product in Maritimes Region. Until then, we propose the use of the Open Data record
558 for the Maritimes RV surveys (DFO 2021) as a precursor to the public web-based marine spatial
559 planning atlas.

560 5 Acknowledgements

561 We thank all the dedicated personnel involved in running trawl surveys in the Maritimes Region
562 and the numerous colleagues in Maritimes Region that have shared information and advice in
563 support of this report. The efforts of the Gulf Region secondary publications coordinators Alicia
564 Cassidy and Jeff Clements in getting this report published are well appreciated.
